

Towards More Reliable Energy Measurements

Scaling Characteristics of $M > 5.8$ earthquakes

Xyoli Pérez-Campos

Gregory C. Beroza

Shri K. Singh

Introduction

- Seismic energy can be estimated using different techniques and different types of data
- In the past:
 - Each of them gave a different value of E_s for the same event
 - Questions on the corrections applied
- Important that before a definite conclusion is drawn, we get consistent and more reliable estimates of seismic energy

Introduction

- Now:

- We are able to get more consistent and reliable values of E_s
 - We include some corrections, overlooked or simplified before
 - We improve the teleseismic estimation by using a weighting technique that takes into account the uncertainty in the parameters and corrections

Teleseismic vs Regional

- Regional estimates larger than teleseismic
- Up to one order of magnitude difference
- Difference independent of focal mechanism

Singh and Ordaz [1994]

Mayeda and Walter [1996]

How do we reconcile these estimates?

- Fundamental measure is the integral of squared velocity spectrum

- In general, **larger differences at high frequencies**

Site Effect

- Correction for combined effect due to amplification and attenuation produced by a rock at the station [*Boore and Joyner, 1997*]

- Need to know the velocity model at the station

Boatwright et al. [2002]:

- **Regional: Generic-rock model**
- **Teleseismic: Hard-rock model**

- Lack of site correction can produce overestimation of E_s

Teleseismic Attenuation

Regional Attenuation and Geometrical Spreading

- Use of regional attenuation models previously obtained by other authors
 - Shallow earthquakes [*Ordaz and Singh, 1992*]
 - Similar trajectories
 - Intermediate earthquakes [*García Jiménez, 2001*]
 - Same events and stations
- Regional attenuation was modeled assuming a frequency independent geometrical spreading
- No systematic behavior of residuals with distance

Preferred Corrections: Site Effect & Attenuation

- Using a site effect correction and modified teleseismic attenuation model, the **spectra become closer to each other**

Discrepancy Reduced

Measure of Discrepancy

Scaling

Focal Mechanism Dependence

Scaling for Strike-Slip

Scaling for Reverse

Scaling for Normal

Conclusions

- Uncertainties in the estimation of E_s can be included, which give us a better knowledge of the uncertainty when estimating it
- More reliable and consistent values of E_s are now estimated
- When analyzing $M > 5.8$ earthquakes, there is no statistical significant scaling of E_s with M_0

How Significant?

- Statistically significant?
- Physically significant?
- Enough data?
- Enough information?
